

# Yalep: from high-school to competitive exams

Frédéric Tran-Minh & Sébastien Lahaye

Grenoble INP - UGA & IRIF, CNRS, PiCube, Malinca, Université Paris Cité

LiberAbaci Meeting, IRIF, Paris, April 2026

Yalep: Yet Another Learning Environment for Proof<sup>1</sup> Frédéric Tran Minh under the supervision of Laure Gonnord and Julien Narboux

A proof assistant in high-school experiment lead by Zoé Mesnil, Frédéric Tran Minh, Iro Bartzia and Julien Narboux

A propositional logic course that is both readable and mechanically verified Sébastien Lahaye under the supervision of Pierre Letouzey and Julien Narboux

---

<sup>1</sup>Frédéric Tran Minh, Laure Gonnord, and Julien Narboux (2026). “A Lean-based Language for Teaching Proof in High School”. In: *Intelligent Computer Mathematics*. Ed. by Valeria de Paiva and Peter Koepke. Cham: Springer Nature Switzerland, pp. 447–467

- teach the concept of proof to high-school students and undergraduates
- ... making them write their own proofs in a proof assistant
- ... thus provide a language readable and writable by this audience

# Yalep : Yet Another Learning Environment for Proof

Yalep main features:

- Syntactic layer above Lean
- Intentionally restricted vocabulary with a "natural" flavor<sup>2</sup>
- Automation enabling acceptable proof granularity
- Custom implementation of "unique number type"<sup>3</sup>
- Formalization of 'type-partial' functions

---

# "Yet Another Learning Environment for Proof" (YALEP) - A first taste

## Theorem

**Assumptions:** (for all integer  $n$ ,  $n$  is even or  $n$  is odd)

**Conclusion:** for all integer  $n$ ,  $n*(n+1)$  is even

## Proof

let  $n$  be an integer

- ◆  $n$  is even or  $n$  is odd
- ◆ if  $n$  is even then  $n*(n+1)$  is even

proof

assume  $n$  is even

- ◆  $n*(n+1)$  is even by product\_even

□

- ◆ if  $n$  is odd then  $n*(n+1)$  is even

proof

assume  $n$  is odd

- ◆  $n+1$  is even
- ◆  $n*(n+1)$  is even by product\_even

□

- ◆  $n*(n+1)$  is even

□

# Favoring forward chaining

## Forward chaining

let  $n$  be an integer

- ◆  $n$  is even or  $n$  is odd
- ◆ if  $n$  is even then  $n*(n+1)$  is even
  - proof
    - assume  $n$  is even
      - ◆  $n*(n+1)$  is even by `product_even`
    -
  - ◆ if  $n$  is odd then  $n*(n+1)$  is even
    - proof
      - assume  $n$  is odd
        - ◆  $n+1$  is even
        - ◆  $n*(n+1)$  is even by `product_even`
      -
  - ◆  $n*(n+1)$  is even

- Forces students to make their goals explicit
- Relaxes constraints on order
- Requires less vocabulary

## Backward chaining

Fact `f1`:  $n$  is even  $\vee$   $n$  is odd

from `every_integer_is_even_or_odd`

We discuss depending on whether

$n$  is even or  $n$  is odd

Assume that `h1`:  $n$  is even

We conclude by `product_even`

applied to  $n$  and  $(n+1)$  and `h1`

Assume that `h2`:  $n$  is odd

We rewrite using `mul_comm`

We apply `product_even`

We conclude by `successor_odd`

applied to  $n$  and `h2`

- Automatic opening of several goals
- Order of sub-goals imposed
- Appropriate vocabulary needed

# Favoring forward chaining

## Forward chaining

# Hiding types : a proof of $\sqrt{2} \notin \mathbb{Q}$ in Yalep

Theorem `sqrt_2_is_irrational` " $\sqrt{2} \notin \mathbb{Q}$ "

Conclusion:  $\sqrt{2}$  is not rational

Proof

assume that  $\sqrt{2}$  is rational

- ◆ there exists an integer  $p$  such that there exists a natural number  $q$  such that  $q \neq 0$  and  $\sqrt{2} = p/q$  and the statement ( $p$  is even and  $q$  is even) is false

obtain such  $p$

obtain such  $q$

$$\begin{aligned} \odot p^2 &= (p/q)^2 * q^2 \\ - &= (\sqrt{2})^2 * q^2 \\ - &= 2 * q^2 \end{aligned}$$

- ◆  $p^2$  is even
- ◆  $p$  is even by `n2_even_implies_n_even`
- obtain an integer  $k$  such that  $p = 2*k$
- ⊙  $q^2 = (2*q^2)/2$ 
  - $= p^2 / 2$
  - $= (2*k)^2 / 2$
  - $= 2 * k^2$
- ◆  $q^2$  is even
- ◆  $q$  is even by `n2_even_implies_n_even`
- ◆ Absurd

□

## Theorem

□

◆  $n*(n+1)$  is even

□

Finds relevant assumption; eliminates  $\forall$  in it

Applies specified lemma to relevant assumptions in context

The lemma gives  $(n+1)n$  even. Unifies with  $n(n+1)$  by commutativity.

Eliminates 'or' in relevant assm

- 9th-graders (3ième) 2 hours session during internship at IRIF
- 10th-graders (Seconde), 6 hours during internship at IRIF
- First year (ESISAR, engineering school in Valence)
- **10th-graders (Seconde) in a high school in Paris**

# A "real-life" experiment with 10th-grade students

## Pedagogical context:

- 10th-graders : 2 groups of 35 pupils; 1 group "with Yalep" + 1 group "without"
- Classes directed by their teacher (Zoé Mesnil)
- 4 x 55 minutes **including lectures about proof**, spread over 1 week

## IT context:

- unmodifiable machines

## Outputs:

- pre-test (student conception of proof)
- post-test (marked evaluation)

## Sessions 1 and 2

- context, goal
- introduction of "for all" and "if then"
- introduction and elimination of "there exists"

- for all integers  $n$ , if  $n$  is even then  $n - 3$  is odd
- for all integers  $n$ , if  $n$  is odd then  $n + 1$  is even

## Sessions 3 and 4 : negation, contrapositive

- for all integers  $n$ , if  $n^2$  is even then  $n$  is even
- for all integers  $n$ , if  $n$  is odd then  $n$  is not multiple of 4

Were planned but not worked out : case disjunction, irrationality of  $\sqrt{2}$

- Pro:
- interest of students in practical work
  - most students try something, contrary to on paper
  - gamification : some pupils wanted to complete the exercise
  - possible because Yalep was available as a Web service

- Cons:
- some technical difficulties with time and material constraints
  - too short due to time constraints
  - issues without textual input (eg: typing \ or ^ ... ; case sensitivity)
  - heavy resources needed (Yalep/Lean runs on server)

## Evolution:

- Proofs influenced by lexical tokens / vocabulary / syntax of Yalep
- Proofs are more formal ; introduction of forall and implies (let/assume)

Un multiple de 7 est 7 fois  $x$  qui est un entiers réel. Donc  $7x + 7x$  est forcément un multiple de 7. Par exemple :  $7 \times 2 + 7 \times 10 = 7x \cdot 12 = 84$  qui est un multiple de 7.

## Obstacles:

- existential quantifier:  
explicit elimination and introduction
- meaning of variables
- literal calculations

pour tout entier  $n$ , si  $n$  est pair alors  $5n + 3$  est impa

Soit  $n$  un entier, supposons que  $n$  est pair  
Prouvons que  $5n + 3$  est impair.

♦ Il existe un entier  $k$  tel que  $n = 2k$  donc

$$5n + 3 = 5(2k) + 3$$

$$♦ 5(2k) + 3 = 10k + 3$$

$$= 2(5k + 1) + 1$$

♦ il existe un entier  $p$  tel que  $p = (5k + 1)$  donc

$$♦ 2(5k + 1) + 1 = 2p + 1$$

Donc  $5n + 3$  est impair.

- Yalep designed for high-school pupils and undergraduates
- Tested in real conditions with parity of numbers
- Also covers : induction, functions, sequences, limits (as demo)
- Never designed to teach logic ...

- Starting a PhD about the use of proof assistants for teaching maths and computer science in *CPGE*.
- Starting with an easy chapter: propositional logic.
- Using YALEP, in order to have a low entry barrier.
- Pre-requisite: definition of data structures (algebraic datatypes), definition of functions using pattern matching and recursion

## MPI/MP program

- Syntax of propositional logic
- Proofs by structural induction
- Semantics of propositional logic
- Meta-theorem of deduction
- Negative normal form, CNF and DNF
- Substitution
- Partial evaluation and indistinguishability lemma
- Natural deduction
- Quine's algorithm

## Exercises and (part of) two competitive exams:

- ENS 2024  
Informatique C; MPI
- CCINP 2021  
Informatique; MP

- The language of propositional logic is:  $V^0$ ,  $F^0$ ,  $Non^1$ ,  $Et^2$ ,  $Ou^2$  (implication and equivalence are defined as derived connectives).
- Variables are represented as natural numbers (not as strings).
- NNF, CNF and DNF are defined as functions to an ad-hoc type (not a subset of propositional formulas).
- NNF transformation uses the dual transformation to ensure termination.
- Quine's algorithm is defined on propositional formulas (not on clauses).
- For natural deduction, context is a list of propositions not a set.

## CCINP 2021

### Content

- Satisfiability of Horn clauses

### Challenges

- Some implicit statements

## ENS 2024

### Content

- Satisfiability of a class of formulas
- Complexity

### Challenges

- Graph theory
- Iterative algorithms

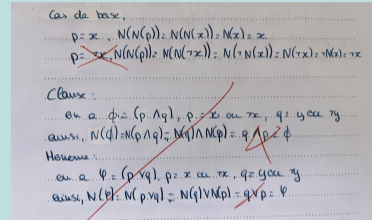

## Exercise:

We consider the function  $N$  defined on propositional formulas by:

- $N(x) = x$
- $N(\neg f) = \neg N(f)$
- $N(f \wedge g) = N(g) \wedge N(f)$
- $N(f \vee g) = N(g) \vee N(f)$

Prove by structural induction that for all formula  $f$ ,  $N(N(f)) = f$ .

## Student answer:

## Common mistakes:

- Confusion between variable denoting variable/formula.
- Confusion between structural induction on NNF/arbitrary formula.

- Formulas are defined as an inductive type, therefore many proofs are done by structural induction on formulas.
- The `induction` tactic helps to complete an induction by automatically generating the induction hypothesis and the case analysis.
- Yalep forces us to write the induction hypothesis explicitly, and to write each case of the proof separately.

# Lean : efficient formalization but less explicit

```
def N f :=  
  | match f with  
  | Var x => Var x  
  | Non g => Non (N g)  
  | Ou g d => Ou (N d) (N g)  
  | Et g d => Et (N d) (N g)  
  | _ => f
```

Implementation of  $N$  in Lean

```
theorem N_involutif' :  
  N (N f) = f := by  
  induction f; repeat simp [N]; repeat tauto
```

- Short proof using the `induction` tactic.
- Proof assistant silently generates the induction hypothesis.
- Solves many cases at once.

```
Exercice N_involutif
Hypothèses: (f : formule)
Conclusion: (N (N f) = f)
Démonstration
posons P := fun f => N (N f) = f
♦ ∀ s, P (Var s)
♦ ∀ g, P g → P (Non g)
  preuve
  soit g : formule
  supposons P g
  ⊗ N (N (Non g)) = N (Non (N g))
  | - = Non (N (N g))
  | - = Non g
  ■
♦ ∀ g d, P g → P d → P (Ou g d)
  preuve
  soit g : formule
  soit d : formule
  supposons P g
  supposons P d
  ⊗ N (N (Ou g d)) = N (Ou (N d) (N g))
  | - = Ou (N (N g)) (N (N d))
  | - = Ou g d
  ■
♦ ∀ g d, P g → P d → P (Et g d)
  preuve
  soit g : formule
  soit d : formule
  supposons P g
  supposons P d
  ⊗ N (N (Et g d)) = N (Et (N d) (N g))
  | - = Et (N (N g)) (N (N d))
  | - = Et g d
  ■
♦ ∀ f, P f par induction structurelle
■
```

- Long proof, where the word induction appears late.
- Have to write the induction hypothesis ourselves.
- We see how each case is solved.

## 2.2.2. Tautologie

On peut définir de même la propriété de tautologie de la façon suivante.

### ▼ Définition : Tautologie

Une formule  $f$  est une tautologie si, pour toute valuation, elle est évaluée à vrai. Autrement dit, toute valuation est un modèle de  $f$ .

### ▼ Tautologie en Lean

```
def tautologie (f : formule) := ∀ (v : valuation), v ⊢ f
```

► Exemple :  $V$  est une tautologie

### ▼ Exemple : Pour tout $s$ , $f_{em}(s)$ est une tautologie

En effet, si l'on prend  $v$  une valuation, une disjonction de cas sur la valeur de  $v$  sur  $s$  permet de conclure.

### ▼ Preuve formelle :

```
Exemple fem_est_tautologie
Hypothèses: (s : Nat)
Conclusion: (f_em s) est tautologie
Démonstration
soit v : valuation :=
  • v s = true ou v s = false :=
  • v [ f_em s ] = v [ Ou (Var s) (Non (Var s)) ] :=
  • v [ f_em s ] = (v [ Var s ] || (v [ Non (Var s) ])) :=
  • si v s = true alors v [ f_em s ] = true :=
  • si v s = false alors v [ f_em s ] = true :=
  on conclut par disjonction de cas :=
  ■
```

► Exemple : Les variables propositionnelles ne sont pas des tautologies

### ▼ Exemple : Pour tout $s$ , $f_{em}(s)$ est une tautologie

En effet, si l'on prend  $v$  une valuation, une disjonction de cas sur la valeur de  $v$  sur  $s$  permet de conclure.

### ▼ Preuve formelle :

```
Exemple
Hypoth (s : Nat) : formule
Conclusion: (f_em s) est tautologie
Démonstration
soit v : valuation :=
  • v s = true ou Definition of example
  • v [ f_em s ] = v [ Ou (Var s) (Non (Var s)) ] :=
  • v [ f_em s ] = (v [ Var s ] || (v [ Non (Var s) ])) :=
  • si v s = true alors v [ f_em s ] = true :=
  • si v s = false alors v [ f_em s ] = true :=
  on conclut par disjonction de cas :=
  ■
```

### ▼ Formule du tiers exclu

```
def f_em (s : Nat) := Ou (Var s) (Non (Var s))
```

# An online course with Verso and Lean4Web

▼ Exercice : Dérivation du tiers exclu

À l'aide de ces règles, démontrer que le théorème du tiers exclu est valide, c'est à dire que la formule  $\text{Ou } \text{Non } \text{E}$  se déduit à partir du contexte vide.

En d'autres termes, donner une preuve de  $\vdash f \vee \neg f$ .

Experimental (Local)

### Yalep:

- enabled high school pupils to practice proof in a highly constrained context
- could be made even more accessible

### Future work:

- conduct a deeper analysis of experiment outputs
- improve, configure automation
- provide better feedback
- cover wider high school curriculum

Try it!      <https://yalep.informatique.u-paris.fr/>

Git:         <https://gricad-gitlab.univ-grenoble-alpes.fr/yalep/Yalep>

- Readable formalization of propositional logic (low entry barrier)
- Force students to make their goals explicit
- Interactive online material of the course

Future work:

- Introduce the tools to students
- Tackle more complex chapters of the mathematics curriculum
